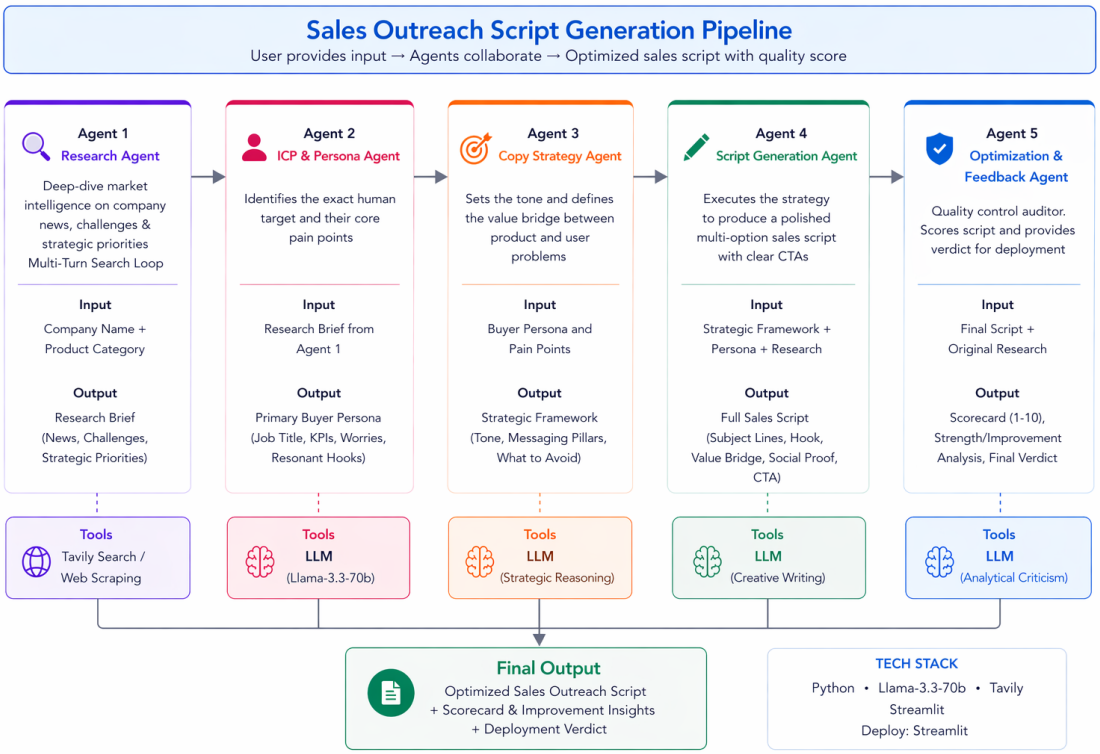
Problem Statement

Sales and B2B outreach teams often struggle to create highly personalized, research-backed outreach at scale. Generic templates fail to resonate with technical stakeholders, while manual research is slow and creates bottlenecks.

The Goal:

Build a multi-agent AI system that automates the entire sales engineering pipeline. Given a target company and a product, the system must perform deep-market research, identify the Ideal Customer Profile (ICP), develop a tailored communication strategy, generate a high-conversion script, and critically audit the final output—all without human intervention.

Why Agentic?


Each stage requires a specialized "brain" from real-time web searching to technical persona mapping and creative copywriting. A single prompt cannot maintain the depth required for all these steps. An agentic architecture allows each specialist to own a discrete task, passing structured intelligence down the pipeline to ensure the final script is grounded in real-world business data.
